CS-360 Weight Tracking App Launch Plan Getz

App Description

In project one, we covered the purpose of our app and what kind of users may be interested in using it. Our listing should appeal to various kinds of users depending on what they use it for. The Google Play Store allows you to have up to 50 custom listings for our app. Each of these listings can be tailored to different users with different needs (Google Play Console, n.d.). The identified users we found in project one were; athletes, general wellness and people trying to lose weight, and professionals (Getz, 2026).

To make the most of our app, I believe it would be best to create one core listing then build upon that based on these three types of users. Let us start with the core listing going from top to bottom. The title of the app should be kept simple. Weight Tracker or Weight Log is a perfect name for the app. The more obvious the keyword, the easier people can find the app. There are a few more things we can do to improve discoverability; we can add screenshots or videos of our app to our listing and graphic assets. To help the Play Store promote our app, we should categorize it under “health and fitness.” We also should set a content rating; our app does not include sensitive content, and any age could use it. We can set the content rating for everyone. However, a child under 13 would likely be bored by our app and not use it. For our app to reach more audiences, we can align our strings with Google's translation services so people in different languages can use the app. Lastly, we should set our description and icon for our listing. It is best to keep our icon simple; users will not look at it for long anyway. A simple weight scale or similar would suffice. The description could be something like “Whether you are trying to lose weight or are an athlete, Weight Tracker is designed to help you reach your goals. Our minimalist design reduces clutter and lets you easily track your progress. Set your goal

weight and receive a special notification upon reaching your goal weight. With a clean grid view, you can track your progress when and wherever you are. No ads, no distractions; only progress.” We can customize these core parts of our listing to appeal to different audiences after some more research. Doing analysis such as A/B testing would be beneficial to see which users are most using our app (Google Play Console, n.d.).

Android Versions

The app will run on most android devices (95+%). We built the app using API 38 or android version 16 (Baklava). The minimum version this app will run on is API 24 or android version 7 (Nougat) (Android Developers, 2025).

App Permissions

The weight tracking app uses a few permissions. Some of which are categorized as dangerous, so we must ask the user for permission. The base app, however, does not require asking the user for these permissions and will work without them. To send SMS notifications, we need to ask for a few such as SEND_SMS, reading the phone state to get the phone's cell phone number, READ_SMS, and reading phone numbers. These permissions are optional by users but allow us to send SMS notifications when they enable them. We have also included that these are not required permissions for the app store so our app can be used on devices without a SIM card or cellular network. Our app does not ask for permission to use the internet, read files, biometrics, or post notifications. These permissions are not needed for our app to run (zyBooks, 2026).

App Monetization

There are many ways we can make money from our app. We can do ads, sponsorships, sell the code, or make a premium version. Ideally, our app is free to download as most people are

unlikely to pay for the app outright. Ads are quite simple to add to our app and give us a small source of income. We could also include the option to pay a small fee such as \$5 to remove ads for your account. Getting a sponsorship or partnership would also be a terrific way to make money from the app, but we would need to include many more features. We could also white label or sell the code to others, letting them make their own app or market the app while we own the intellectual property. Lastly, making a premium version is easy to make more money from the app. For example, we could limit the number of entries users can input with the free version. The premium version could include more advanced features such as trend tracking, ad-free, more advanced notifications, or AI integration. I think with the current scope of the app, using ads is the best option. With a little bit more work, making a premium version and letting others re-skin the app would be the next best step (BuildFire Team, 2024).
